

Using Data to Fight Malaria

Sean Nealon, University of California - Riverside

Researchers are using sensors to count and classify insect vectors, producing real-time information to plan suppression programs to fight malaria.

Riverside, CA — The [University of California, Riverside](#) [2] announced today that it is a Grand Challenges Explorations winner, an initiative funded by the Bill & Melinda Gates Foundation. Yanping Chen will pursue an innovative global health and development research project, titled "Using Sensors to Understand Insect-Vectored Diseases and Plan Effective Interventions."

Grand Challenges Explorations (GCE) funds individuals worldwide to explore ideas that can break the mold in how we solve persistent global health and development challenges. Chen's project is one of more than 80 Grand Challenges Explorations Round 11 grants announced today by the Bill & Melinda Gates Foundation.

To receive funding, Chen and other Grand Challenges Explorations Round 11 winners demonstrated in a two-page online application a bold idea in one of five critical global health and development topic areas that included development of the next generation condom, agriculture development, and neglected tropical diseases.

Chen, a computer science Ph.D. student working in the lab of Professor Eamonn Keogh in the Bourns College of Engineering, will use the \$100,000 to create sensors to count and classify insect vectors, producing real-time information that can be used to plan intervention/suppression programs to combat problems such as malaria. She will be assisted by Adena Why, a Ph.D. student in entomology, and

Moses Oben Tataw, who recently earned his Ph.D. under Keogh. The goal is to produce a software system that leverages information from sensors, and can produce real-time counts of the target insects and summarize them in an intuitive and actionable manner.

With sensors already built, the plan now is to further investigate techniques to improve the classification accuracy of the system, to make the sensors more robust and inexpensive, and develop higher level systems and software that will aid health workers and non-governmental organizations. The idea is to create an open-source library of insect wingbeat signatures, circadian rhythms and other behaviors that can be used by researchers worldwide. Already, using a makeshift insectary in Keogh's computer science lab, the researchers have collected a few hundred thousand observations. In the future, they expect to collect at least tens of millions more. They then plan to do field tests and demonstrations in Cameroon and Cambodia and/or Thailand.
